Vinnot Hever not merely with one, but with two good silos.

ISSUED BY THE State Board of Health OF MARYLAND.

When Typhoid Fever appears in a be looked for in drinking water or food producing capacity of the farm at The patient may not have been infected 160-acre farm with a silo will produce at home, but if a second case occurs this as much revenue as one of 180 acres be traceable to the first patient. In a without. Therefore, the first cost of

of your drinking water. You can do this by asking your local better to buy a health officer for instruction about shipoing us samples of your drinking water. The daily supply of drinking water should

The infectious material of typhoid fever is produced in but one way. It grows always in the bowels and some. times in the bladder. It, therefore, escapes from the sick person in the stools and urine. If we kill the germs in the stools and urine as soon as they are passed, there can be no spread of typhoid fever. These discharges should, therefore, be disinfected as soon as possible. You will need a large quantity of a good disinfecting solution.

RECEIPT FOR A GOOD DISINFECTANT. To four gallons of water add enough salt to make a strong brine. Put this in a five-gallon demijohn or jug and add a quart of crude carbolic acid. Shake it up well and you will have a good disinfectant for stools and urine.

The crude carbolic acid, known as U 3. P. 90 per cent., is very good, and a quart will cost about 50 cents. There is a cheaper grade, known as a 36 per cent. acid, which is nearly as effective. About a pint of this solution should be put in the chamber or bed pan before it is used, so that the discharges will begin to be disinfected as soon as they leave the body. There must always be at least as much of the disinfecting solution as there is of the discharges, so that more of the disinfecting solution may need to be added after the discharges are passed. If the stools are thin and watery, their disinfection will be accomplished in half an hour or so: but if the stools are thick or formed very much more time will be required. On that account it is best to have a covered jar or bucket into which the bed pan can be emptied, and to empty this jar only once in 24 hours. If the discharges cannot be finally thrown into a sewer, they should be buried in the soil at a convenient spot where there is no chance of their fouling a water supply. The discharges should never be thrown upon the surface of the ground, for you will hardly be successful in killing all the typhoid bacilli, and you must not place them where those not killed by the acid may be blown about in the

other people. In spite of every precaution those who wait on the sick person will get their hands infected, and it is therefore necesary to wash the hands every time one loes any service about the patient's bed or body. Whoever waits on the patient must not prepare food ar drink for other persons in the house, or if it is impossible to mind this rule, one must most carefully and thoroughly cleanse the hands before performing any household duty outside the sick room. Good scrubbing with soap, water and a brush, and then rinsing well in fresh water, will suffice for cleansing the hands.

dust or carried away by flies to infect

If anyone else in the house falls sick within two weeks after the first patient, the probability is that the infection was dged before the precautions were taken n regard to drinking water and the dismade a mistake somewhere in our pre-
